Called "a useful contribution to the current literature on corrosion science, engineering, and technology" by Corrosion Review, this book offers real-world applications and problem-solving techniques to reduce the occurrence of pits, cracks, and deterioration in industrial, automotive, marine, and electronic structures. It details the electrochemic This textbook is intended for a one-semester course in corrosion science at the graduate or advanced undergraduate level. The approach is that of a physical chemist or materials scientist, and the text is geared toward students of chemistry, materials science, and engineering. This textbook should also be useful to practicing corrosion engineers or materials engineers who wish to enhance their understanding of the fundamental principles of corrosion science. It is assumed that the student or reader does not have a background in electrochemistry. However, the student or reader should have taken at least an undergraduate course in materials science or physical chemistry. More material is presented in the textbook than can be covered in a one-semester course, so the book is intended for both the classroom and as a source book for further use. This book grew out of classroom lectures which the author presented between 1982 and the present while a professorial lecturer at George Washington University, Washington, DC, where he organized and taught a graduate course on "Environmental Effects on Materials." Additional material has been provided by over 30 years of experience in corrosion research, largely at the Naval Research Laboratory, Washington, DC and also at the Bethlehem Steel Company, Bethlehem, PA and as a Robert A. Welch Postdoctoral Fellow at the University of Texas. The text emphasizes basic principles of corrosion science which underpin extensions to practice.

"There exist many systems in Nature which present overall behavior of great complexity. Yet research in chemistry and physics has shown that the fundamental components of many systems are quite simple. The observed great complexity has its origin in the simple interactions between fundamental components. For example, corrosion of metals in aqueous environments involves elemental particles such as metal atoms, water molecules, and ions in the solution. Each elemental particle interacts with neighboring species according to the rules of Nature. When large amounts of these individual reactions act together, diverse corrosion phenomena of great complexity are generated. Conceptually, if a simulation correctly implements the interactions between species, system behaviors should spontaneously arise from the simulation. The molecular automation developed in this work takes the approach of Nature to model the local interactions between individual particles, allowing corrosion phenomena to emerge spontaneously as outcomes of the simulation. Atoms, molecules, and ions are simplified to be particles of no size or weight. Each particle interacts with neighboring species based on the local information regarding its immediate neighbors. Species interactions are represented as thermally activated events which occur probabilistically, mimicking the thermal activation mechanism so prevalent in Nature. A set of rules that imitates the process of Nature is developed to govern the reactions between species. Since corrosion is an interfacial phenomena which considers both the solution and the metal phase, this work addresses the applications of molecular automation to the physical chemistry in solutions, the distribution of electrons in metals, and finally the structural features of the electrical double layer. Both two-dimensional and three-dimensional models have been developed. Parallel computation using Nvidia's graphics processing unit (GPU) and compute unified device architecture (CUDA) platform is employed to accelerate the computation. Simulation results presented in this work, including the ionic activity coefficients, corrosion reaction kinetics represented by the Tafel behavior, concentration polarization, pitting, surface deposition, distribution of

electrons, and the electrical double layer, etc., are all emergent behaviors that spontaneously evolve from repeated elementary interactions between individual particles"--Leaves v-vi.

The global economic cost from corrosion is estimated to be more than US\$2.5 trillion, or equivalent to 3.4% of the global GDP. Corrosion costs the U.S. economy close to \$300 billion per annum. About 100 billion dollars these costs could be remediated by application of corrosion-resistant materials and the use of corrosion-related technical practices such as corrosion inhibitors. A corrosion inhibitor is a chemical compound that, when added to a liquid or gas, decreases the corrosion rate of a metal, or its alloy that comes into contact with the fluid or vapour. These chemicals are both organic and inorganic compounds, which generally form a protective layer on the metal surface. Some corrosion inhibitors contain heavy metals are harmful to human health, toxic to plants, environments, and animals. They also have adverse effect on the ecology of the receiving environment and on surface and ground water quality. This book focuses on the use of Vapro VBCI Corrosion Inhibitors which are biodegradable, less toxic, and environmentally friendly.
